

Food Delivery App: Funnel & A/A/B Font Test

How far users get through the purchase journey, and whether a font change moved the needle

Context

A food delivery startup logs every user action in its app, from opening the main screen through to a completed payment. Two questions matter for the business: where do users drop out of that journey, and did a recent font change affect how they move through it?

7,534

users in the 7-day analysis window

Food Delivery App · Portfolio Project

240,887

events logged, Aug 1–7, 2019

3

experimental groups: 2 control, 1 test
(new font)

Two analyses, one dataset

PART 1

Conversion funnel

- Main screen → Offers → Cart → Payment
- Unique users per step, not raw event counts
- Step-to-step and cumulative conversion
- Order validated against first-touch timestamps

PART 2

A/A/B font test

- A/A check: control 246 vs. control 247
- A/B: test group 248 (new font) vs. each control
- Two-proportion z-test per funnel event
- Bonferroni correction across all 20 tests

Where users drop out

THE MAIN OPPORTUNITY

~38%

of users who view the main screen never move on to the offers screen — by far the steepest drop in the funnel. Every later step converts above 80%.

Why an A/A/B, not just an A/B

Before trusting a test-vs-control comparison, we first checked that the two control groups — both on the old font — behaved the same as each other. That's the "A/A" step: it validates that the traffic split itself is reliable.

Food Delivery App · Portfolio Project

Result: no significant difference between 246 and 247 on any of the 5 events (all $p > 0.11$) — the split was reliable, so the A/B comparisons that follow can be trusted

15 comparisons, zero significant results

p-values, test group (248) vs. each control — all well above 0.05

Event	246 vs 248	247 vs 248	Combined vs 248
Main screen	0.295	0.459	0.294
Offers screen	0.208	0.920	0.434
Cart	0.078	0.579	0.182
Payment	0.212	0.737	0.600
Tutorial	0.826	0.765	0.765

Lowest p-value across all 15 test-vs-control comparisons: 0.078 (Cart, group 246 vs 248) — still far above the 0.05 significance level, before any correction for multiple comparisons.

Correcting for 20 tests

5 events $\times$ 4 group comparisons (A/A, 246 vs 248, 247 vs 248, combined vs 248) = 20 hypothesis tests in total.
Running that many tests raises the odds of a false positive by chance alone, so the significance threshold is corrected down with a Bonferroni adjustment.

Standard threshold

0.05

Bonferroni-adjusted ($\div 20$)

0.0025

CONCLUSION

The font change is safe to ship — the funnel is where the real opportunity is

Font (A/A/B test)

No statistically significant effect on any funnel event, even before correcting for 20 comparisons.

Funnel

~38% of users drop off between the main screen and the offers screen — the clearest place to focus product work.
